² Institute of Biology, Scientific Research Centre of the Slovenian Academy of Sciences and Arts, Novi trg 2, SI-1000 Ljubljana, Slovenia

Abstract – In the spring and summer of 2010 a number of new localities of the southeastern-Alpine endemic *Leontodon hispidus* subsp. *brumati* were found on temporarily flooded riparian rocks in the gorge of the Sava River between the village of Sava and Zidani Most (central Slovenia). The species has so far been known only in northeastern Italy and western Slovenia (the Soča valley). In order to obtain more specific information its sites were studied phytosociologically and the communities in which it grows in the Sava and the Soča valleys compared. Two new associations were described on the basis of these comparisons: *Trisetio argentei-Leontodontetum brumati* ass. nov. and *Leontodonti brumati-Seslerietum calciae* ass. nov. As this endemic taxon and its endemic communities are a characteristic of riparian flora and vegetation of some Slovenian mountain rivers and as its localities in the Sava valley are explicitly disjunct and the southeastern-most in the entire known distribution area, they deserve to be studied and protected.

Key words: *Leontodon brumati*, phytogeography, synsystematics, Sava, Soča, Slovenia

Introduction

Leontodon hispidus L. subsp. *brumati* (Schiede ex Reichenb) T. Wraber [*Leontodon hispidus* var. *brumati* (Schiede ex Rchb.) Fiori = *L. brumati* Schiede ex Rchb.] is a southeastern-Alpine endemic, known so far only in the foothills of the Julian and Carnic Alps and along some rivers in the Friuli lowland, western Slovenia and northeastern Italy (MAYER 1952, 1958, 1960; WRABER 1998, 2007; POLDINI 1991, 2002, 2009; JOGAN et al. 2001; ČUŠIN 2001, 2006; ČUŠIN and DAKSKOBLER 2001; DAKSKOBLER 2005). Its localities in Slovenia are on riparian rocks and river boulders in the Nadiža riverbed in the Breginjski kot, on riparian rocks along the Soča River between Bovec and Solkan (relatively often

only along the middle Soča between Podselo and Plave), on similar sites along the Učja River. Reliable sites are only on the Italian side of the former border crossing Učja (WRABER 1998), very likely also downstream in the Slovenian territory, along the rivers Idrija (rarely, Golo Brdo, under Kostanjevica) and the Idrijca (very rarely, a rocky eyot on Slap ob Idrijci, under the dam at the new, small hydroelectric power plant, 9848/4, leg. et det. I. Dakskobler, 30. 5. 2010, Herbarium LJS, relevé 1 in table 2).

During our inventory of the flora in the Sava valley, between the village of Zidani most and Sava, this taxon was found at several spots on riparian rocks on both sides of the river; first on 12 May 2010 on the right bank between Trbovlje and Hrastnik, downstream from the hamlet Ribnik (Doležak) – 9856/3 (leg. I. Dakskobler et B. Vreš); on the same day on the same bank of the Sava downstream from Hrastnik, in the village of Podkraj, between the farmsteads Rus and Tohar (9856/4); two days later, on 14 May 2010, on the left bank of the Sava near Hrastnik – 9856/4 (leg. A. Seliskar). The article presents the localities and sites of this endemic taxon in the Sava valley and the communities in which it grows and compares them with its sites and communities in the Soča valley. The issue of its conservation is discussed in view of the fact that its sites along the Sava are in an area, designated for the construction of new hydroelectric power plants.

Materials and methods

Flora and vegetation along the Sava and the Soča Rivers (Figs. 1, 2) were studied according to the established central-European methods (BRAUN-BLANQUET 1964, EHREN-DORFER and HAMANN 1965). Floristic records and phytosociological relevés were entered into the FloVegSi database (SELIŠKAR et al. 2003). The same application was used to make the distribution map (Fig. 2). When processing the relevés we transformed the combined cover-abundance values with numerical values (1–9) according to van der MAAREL (1979). Numerical comparisons were performed with the SYN-TAX 2000 program package (PODANI 2001). The relevés were compared by means of »(unweighted) average linkage method« – UPGMA and principal coordinates analysis (PCoA). Wishart's similarity ratio was used in all the methods. The nomenclature source for the names of vascular plants is the Mala flora Slovenije (MARTINČIĆ et al. 2007), MARTINČIĆ (2003) for the names of mosses and THEURILLAT (2004) for the names of the syntaxa.

Ecological description of the study area

The study area with *Leontodon hispidus* subsp. *brumati* belongs to the pre-Alpine phytogeographical region (M. WRABER 1969). In terms of landscape regions it forms a part of the Sava valley or, more widely speaking, of the Posavsko hribovje region (PERKO and OROŽEN ADAMIĆ 1998). From Litija towards Zidani Most the Sava initially still runs through a relatively wide valley which narrows at the village of Sava and remains narrow with steep banks throughout its course. On the right bank of the river, up to Hrastnik, runs a regional road, and on the left bank the double track Ljubljana–Zagreb railway. The prevailing geological bedrock consists of Triassic dolomite and limestone, in some sections (in the vicinity of Litija, Podkraj pri Hrastniku) also Permian–carbon slate claystones and sandstones (BUSER 1990). The climate is moderate continental. Mean annual air temperature in

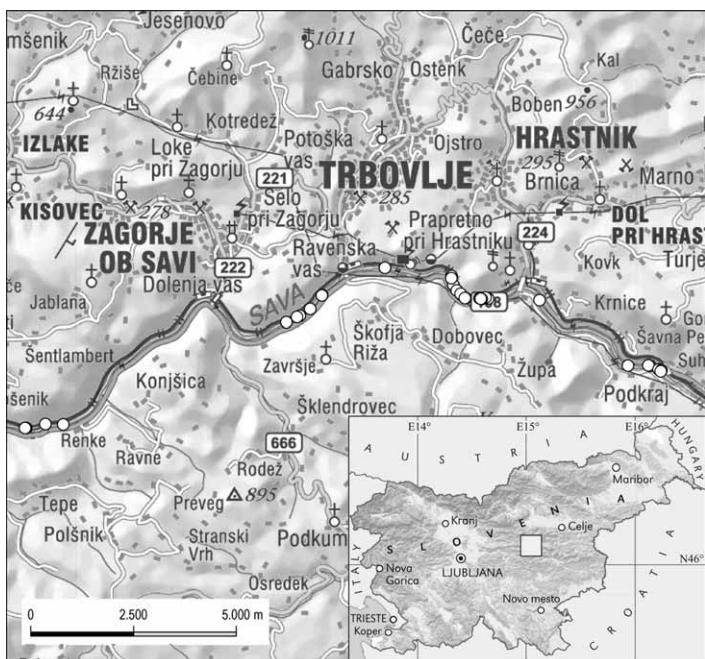

Fig. 1. Distribution of the taxon *Leontodon hispidus* subsp. *brumatii* in Slovenia with new localities in the Sava valley.

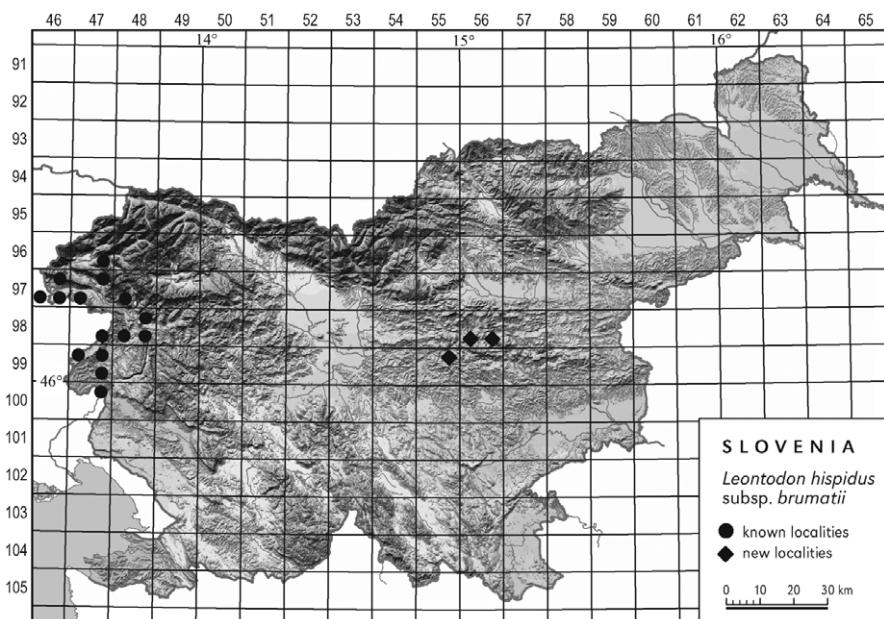

Fig. 2. Localities of the taxon *Leontodon hispidus* subsp. *brumatii* in the Sava valley (central Slovenia).

the period 1961–1990 was between 8 °C and 10 °C, mean January temperature –2 °C to 0 °C and mean July temperature 18 °C to 20 °C (CEGNAR 1998). Mean annual precipitation in the same period was between 1200 mm and 1400 mm (ZUPANČIĆ 1998). The Sava River is torrential in this section and its level rapidly increases after heavy rain; rocky ledges along the river are partly or entirely flooded at least ten times a year (Fig. 3). Normally, there is a short period in May when the water level is low, and a longer period favourable for the development of the vegetation in the summer months from July to September (Hydrological data ARCHIVE 2008). Dolomite slopes above the Sava are overgrown with basophilic beech forests (*Ostryo-Fagetum*, *Arunco-Fagetum*, *Hacquetio-Fagetum*), and in areas where clay slates are the dominant bedrock also with acidophilous beech forests (*Blechno-Fagetum*). On the colluvium (hillside scree) in the gorges and at the foot of slopes there are some sites of valuable broad-leaved species (*Hacquetio-Fraxinetum*, *Veratro nigri-Fraxinetum*, *Tilio cordatae-Aceretum platanoidis ostryetosum*). The steepest, rockiest sites at the right bank of the Sava (Reber between the village of Sava and Mošenik; Reber between Zagorje and Trbovlje) are overgrown with basophilic forests of Scots pine and black pine (*Genisto januensis-Pinetum sylvestris*). On similarly steep, rocky sites on both banks of the river there are also sites of the community of pubescent oak and hop hornbeam (*Querco pubescenti-Ostryetum carpinifoliae*). On smaller areas on rare gravel sites grows a community of grey and red willow (*Salicetum eleagno-purpureae*). The banks of the Sava between Litija and Zidani Most have been changed considerably, often reinforced with dry stone walls. Towards Zidani Most the river course becomes noticeably more placid and the banks flooded, due to the dam of the Boštanj hydroelectric power plant downstream. The best preserved natural slopes with rocky ledges are in the gorge between Hrastnik and Trbovlje and it is there that most of localities of *Leontodon hispidus* subsp. *brumatii* were found.

Results

Overview of the new localities of *Leontodon hispidus* subsp. *brumatii* in the Sava valley

9856/3 (UTM 33TWM00) Slovenia, Dolenjska, the Sava valley, the right bank of the Sava downstream from the hamlet of Ribnik (Doležak), riparian rocks and pioneer grey willow stands (*Salicetum eleagno-purpureae*), 200 m a.s.l., leg. et det. I. Dakskobler et B. Vreš, 12. May 2010, Herbarium LJS; the right bank of the Sava, upstream from the hamlet of Ribnik (Doležak) and the outfall of the Ribnik stream into the Sava, 205 m a.s.l. Det. B. Vreš, 8. June 2010.

9856/3 (UTM 33T WM00) Slovenia: Štajerska, Trbovlje, the left bank of the Sava, a rocky ledge at the Trbovlje thermal power plant; also to the east and southeast of this thermal power plant, under Ringa railway tunnel and further on to the foot of the hill Vištov vrh (opposite Ribnik or Doležak), 200 m a.s.l., Det. A. Seliškar, 19. May 2010.

9856/3 (UTM 33T WM00) Slovenia: Štajerska, the Sava valley, Trbovlje, hamlet Za Savo, on several spots on the banks of the Sava under the farmsteads Vrstovšek, Frajle, Frankovič and Kos, 200 m a.s.l. Det. B. Vreš, 27. July 2010.

9856/3 (UTM 33T WM00) Slovenia: Dolenjska, the Sava valley, Mitovšek, Ribogojnica (fish hatchery), riparian rocks on the right bank of the Sava, 205 m a.s.l. Det. B.

Vreš, 26. July 2010; Spodnji Šklendrovec, under the road Prusnik – Mitovšek, 210 m a.s.l.; Det. B. Vreš, 15. September 2010.

9856/4 (UTM 33T WM00) Slovenia: Dolenjska, the right bank of the Sava downstream from Hrastnik, Podkraj, at the homesteads Rus and Tohar and several spots between them (under the Ravenski hrib hill), riparian rocks, 200 m a.s.l., leg. et det. I. Dakskobler et B. Vreš, 12. May 2010, I. Dakskobler et B. Čušin, 17. June 2010, B. Vreš, 26. July 2010 and 7. October 2010, Herbarium LJS.

9856/4 (UTM 33T WM00) Slovenia: Štajerska, Hrastnik, the left bank of the Sava near the hamlet of Za Savo, to the east of the bridge across the river, riparian rocks, 200 m a.s.l., leg. et det. A. Seliškar, 14. May 2010 and 20. July 2010, Herbarium LJS.

9856/4 (UTM 33T WM00) Slovenia: Štajerska, the Sava valley, Hrastnik, the foot of the Višov vrh hill, riparian rocks and ledges on the left bank of the Sava (under the railway track) between Trbovlje and Hrastnik, at several spots, 200 m a.s.l., leg. et det. A. Seliškar et I. Dakskobler, 18. May 2010, Herbarium LJS.

9856/4 (UTM 33T WM00) Slovenia: Dolenjska, the right bank of the Sava to the west of Hrastnik, under the filling station along the main road Zagorje–Hrastnik, 200 m a.s.l. Det. I. Dakskobler et A. Seliškar, 18. May 2010.

9856/4 (UTM 33TWM10) Slovenia: Štajerska, the left bank of the Sava, below the village of Suhadol, flood bank along the Sava, 195 m a.s.l. Det. A. Seliškar, 20. July 2010.

9955/2 (UTM 33TVM90) Slovenia: Dolenjska, the Sava valley, Renke, the right bank of the Sava downstream from Šuštarski most, a bridge across the Sava, 220 m a.s.l., riparian rocks., leg. et det. I. Dakskobler et B. Čušin, 17. May 2010, Herbarium LJS.

9955/2 (UTM 33TVM90) Slovenia: Štajerska, the Sava valley, Mošenik, the left bank of the Sava, to the west of the Šuštarski most (a footbridge), rocks along the Sava, at the outfall of a tufa-forming stream, 220 m a.s.l. Det. A. Seliškar and B. Vreš, 12. October 2010; Mošenik, the left bank of the Sava, to the west of the bridge Šuštarski most, riparian rocks below the abandoned Mars homestead, 220 m a.s.l. Det. A. Seliškar et B. Vreš, 12. October 2010.

Leontodon brumatii was recorded on the banks of the Sava between Litija and Zidani Most at the altitude of 195 to 220 m, at 38 microlocalities in four sections: between the villages of Sava and Zagorje (the westernmost localities are at Renke on the right and at Mošenik at the left bank of the river), between Zagorje and Trbovlje (at Mitovšek on the right and under the hamlet of Za Savo on the left bank of the river), between Trbovlje and Hrastnik (at Ribnik and the Hrastnik filling station on the right bank and at the foot of Višov vrh on the left bank of the river, where it grows abundantly on riparian rocks) and between Hrastnik and Zidani Most or Radeče (the easternmost locality is under the village Suhadol on the left bank and at the homestead Tohar in Podkraj on the right bank) and in three quadrants – 9955/2, 9856/3 and 9856/4 (Figs. 1, 2).

Leontodon hispidus subsp. *brumatii* is an endemic with a small distribution area. There are very few data on the communities in which it grows. It is known to grow on rocks (POLDINI 1991). The subspecies is not discussed on its own but together with *Leontodon hispidus* in the Flora alpina (AESCHIMANN et al. 2004). WRABER (1998) claims that it usually grows in a very characteristic environment, on riparian rocks that are periodically washed by river water. He stresses that the plant can also grow outside the direct influence of the water splashing, which was confirmed in our research in the Soča valley, where the studied taxon was recorded also on rocks and steep gravelly slopes that the river cannot reach even when the water level is at its highest. The specimens growing the highest above the Sava River level were found in a crevice of the retaining wall under the railway track, some 3.5 m above the low spring water level, and on a stony road slope approximately 5 m above the low spring water level. However, even these specimens are flooded when the water level is at its highest.

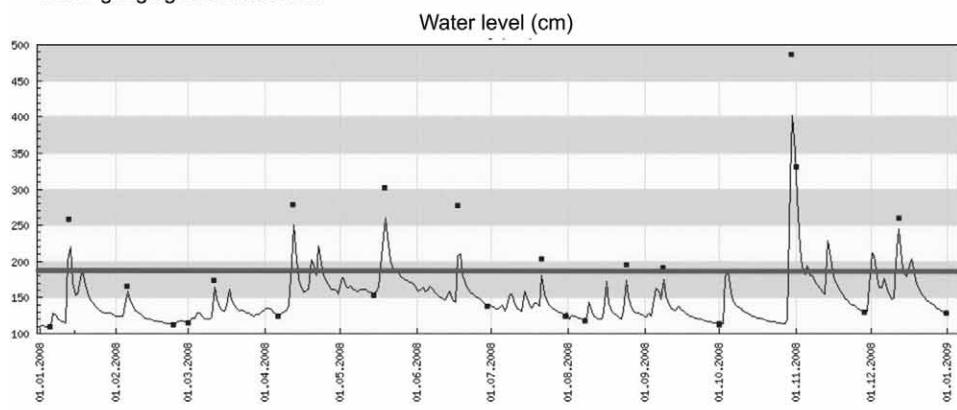

The rivers Soča and Idrijca are torrential and have a similar water regime to that characteristic for the Sava River (Fig. 3). Interesting is the frequent occurrence of the subspecies *L. brumatii* under the Doblar hydroelectric power plant where the fluctuation of the water level and in turn inundation of the subspecies' sites occurs on a daily basis. So far, no comprehensive phytosociological inventory of all its known localities in the Soča valley has been made, but we have made 15 relevés of this species at different locations over a longer time period. These relevés were compared to those from the Sava valley and thus the following results were obtained (Figs. 4, 5).

In all of the comparisons the relevés from the Sava valley (ZS) were grouped separately from the relevés from the Soča valley (PO). Two phytosociological tables were made for both regions (Tabs. 1, 2). 15 relevés made in the Sava valley on the both banks of Sava be-

tween Mošenik and Hrastnik were grouped together (Tab. 1). In this area, *L. brumatii* mainly overgrows riparian rocks, rarely also coarse, riparian gravel, both being at least periodically flooded (Figs. 6, 7). Phanerograms and some moss species grow only rarely on these rocks. In addition to *L. brumatii* the most abundant grass among the phanerograms is *Deschampsia cespitosa*. Other species, which are mostly the character species of cultivated meadows and nitrophilic ruderal communities, have only scattered and individual occurrences. Only three of the relevés in table 1 (relevés 4 to 6) slightly resemble those in the Soča valley (Tab. 2), which is mainly due to the occurrence of *Chamaecytisus purpureus*, *Peucedanum oreoselinum* and *Inula ensifolia*. Even the subspecies *Sesleria caerulea* subsp. *calcaria*, which usually dominates in the relevés in the Soča valley (in addition to *L. brumatii*), is relatively rare on the riparian rocks in the Sava valley and is more abundantly represented in only one relevé. Most stands with *L. brumatii* in the Sava valley are described as a new association *Triseto argentei-Leontodontetum brumatii* ass. nov. In the floristic composition as a whole there are several species which indicate a partial similarity of the studied community with the communities with dominant *Phalaris arundinacea* that overgrow periodically flooded sites immediately along the mid-course of rivers subject to considerable fluctuation of water level and that are classified into the alliance *Phalaridion arundinaceae* Kopecký 1961 and the association *Rorippo-Phalaridetum* Kopecký 1961 (BALÁTOVÁ-TULÁČKOVÁ et al. 1993). So far, this association in Slovenia has been documented with only three relevés (PETRINEC 1999). In addition to its relevés the synoptic table (Tab. 3) includes also the relevés of the same association from the border region between Slovakia and Hungary (HRIVNÁK and UJHÁZY 2003). The synoptic table and numerical comparison of the three syntaxa (Figs. 8, 9) clearly demonstrate that our stands cannot be classified into the association *Rorippo-Phalaridetum*. They comprise only a few of the species diagnostic for the class *Phragmiti-Magnocaricetea* Klika in Klika et Novák 1941 (*Mentha aquatica*, *Lycopus europaeus* and *Phalaris arundinacea*) and only *P. arundinacea*

occurs at a higher frequency, but in modest abundance (mainly +). The decisive factor for the synsystematic classification of the studied stands is therefore the dominant *L. brumatii*, which is characteristic of wet rocks. Based on the available material the most sensible classification of the new association is therefore into the alliance *Cystopteridion fragilis*, order *Potentilletalia caulescentis* and class *Asplenietea trichomanis*, even though no other diagnostic species of the alliance, order and class have been recorded in these stands.

Fig. 6. *Leontodon hispidus* subsp. *brumati* on temporarily flooded riparian rocks in the Sava valley (central Slovenia) (Photo I. Dakskobler).

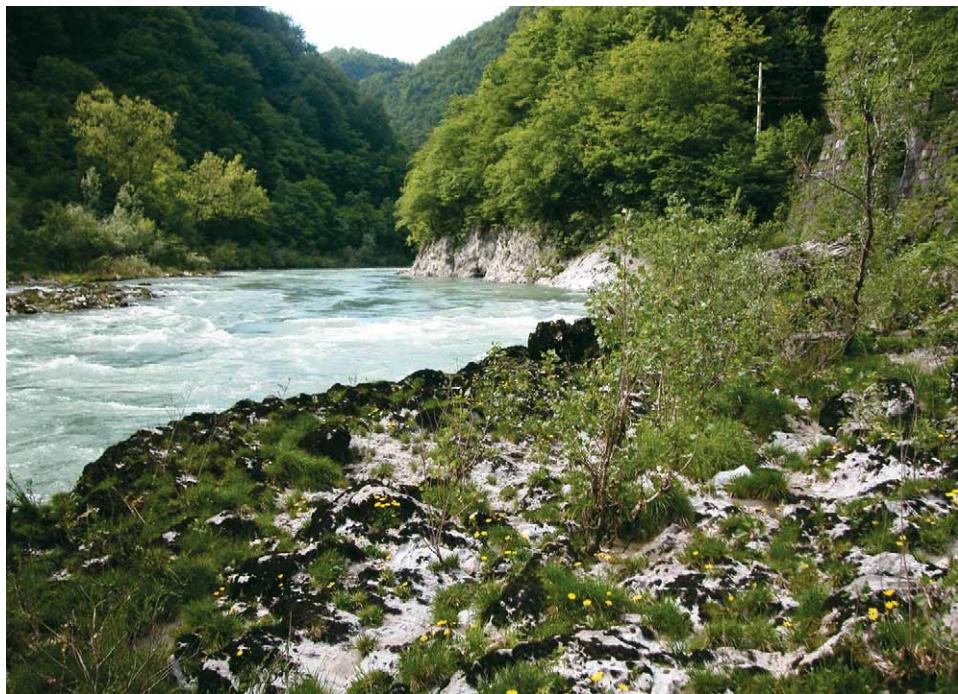

Fig. 7. Typical site (habitat) of the *Triseto argentei-Leontodontetum brumattii* community in the Sava valley (Photo A. Seliškar).

1: *Trisetoo-Leontodontetum* – this paper; 2: *Rorippo-Phalaridetum* – Petrinac 1999; 3: *Rorippo-Phalaridetum* – Hrivinák and Ujházy 2003

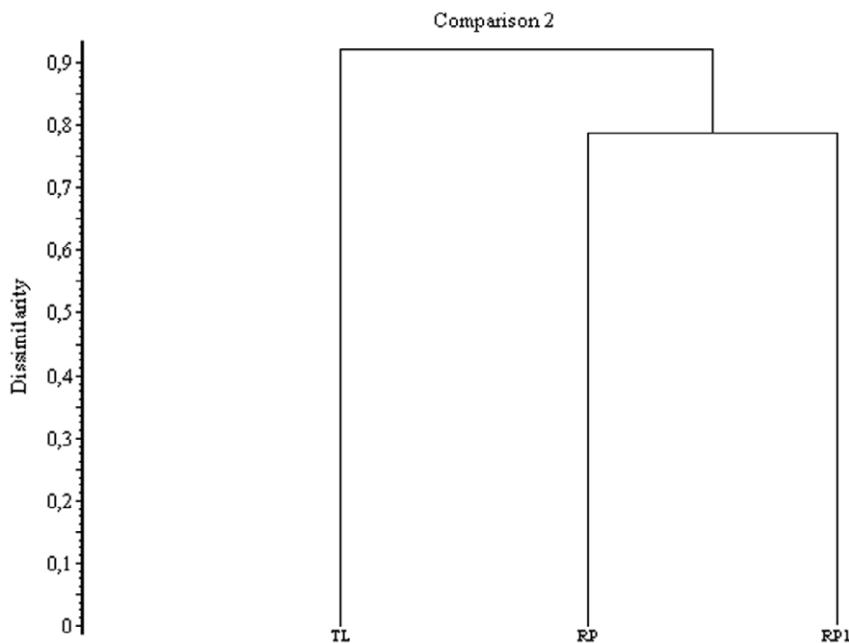

Fig. 8. Dendrogram of the two riparian communities (TL – *Triseto-Leontodontetum*, RP and RP1 – *Rorippo-Phalaridetum*) – UPGMA, similarity ratio.

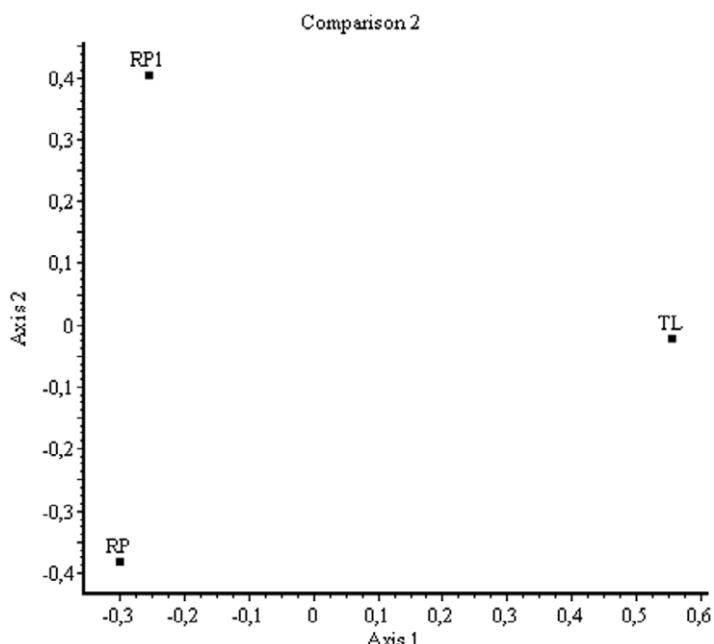

Fig. 9. Two-dimensional scatter-diagram of two riparian communities (TL – *Triseto-Leontodontetum*, RP and RP1 – *Rorippo-Phalaridetum*) – PCoA, similarity ratio.

Diagnostic species of the new association are *Leontodon brumatii* (dominant species), *Trisetum argenteum* and some riparian mosses of which we established two – *Brachythecium rutabulum* and *Cinclidotus fontinaloides*. *Trisetum argenteum* is a character species of scree communities, especially in the subalpine and alpine belts (AESCHIMANN et al. 2004). It is relatively frequently deposited and preserved on riparian rocks along the central or lower course of Alpine rivers, e.g. in Slovenia along the Soča and the Sava, so it is also a good indicator of the site or community of *L. brumatii* on riparian rocks. The nomenclature type of the new association, *holotypus*, is relevé No. 12 in table 1. The new association is subdivided into three variants: the typical (relevés 2 and 3 in table 1); the variant with *Chamaecytisus purpureus* (the differential species are also *Peucedanum oreoselinum*, *Sesleria caerulea* subsp. *calcaria* and *Inula ensifolia*) – relevés 4 to 6 in table 1 – these stands indicate a possible transition into the community *Leontodonti brumatii-Seslerietum calcariae* described hereinafter, i.e. into the initial riparian grassland; and the variant with *Deschampsia cespitosa* (the differential species is also *Phalaris arundinacea*) – relevés 7 to 13 in table 1. Everywhere sand accumulates in the runnels carved into the rocks or in coarse gravel, conditions are created that facilitate successional development towards riparian willow stands with black poplar, which respond particularly well to sufficient amount of fine particles (Božič et al. 2008). The stands of this variant therefore indicate potential successional development into the community *Salicetum eleagno-purpureae* var. *Populus nigra*, into which relevés No. 14 and 15 were classified (see DAKSKOBLER 2010). Individual shoots of tree species *Populus nigra*, *Ulmus laevis* and *Salix alba* occur also in other relevés.

Most of the relevés in table 2 (the Soča valley) are classified into the new association *Leontodonti brumatii-Seslerietum calcariae* ass. nov. Its stands characterize the initial stony riparian grassland on undeveloped soil (lithosol). The species composition belongs to very different phytosociological groups (Tab. 4); the largest, some 21 %, is the

Tab. 4. Structure of the association *Leontodonti brumatii-Seslerietum calcariae* according phytosociological groups (in %).

proportion of species of dry grasslands from the class *Festuco-Brometea* and species of basophilic pine forests from the class *Erico-Pinetea*, followed by chasmophytic species (*Asplenietea trichomanis*), species of subalpine grasslands (*Elyno-Seslerietea*) and thermophilic oak forests (*Quercetalia pubescens*), which have a proportion of 10 %. Varied species composition also indicates a certain similarity with the communities of thermophilic forest edges from the class *Trifolio-Geranietea*, although it features a small proportion of diagnostic species of this class (2.5 %). In support of the synsystematic classification a synoptic table was made (Tab. 5), into which two riparian meadow communities – *Centaureo dichroanthae-Globularietum cordifoliae* Pignatti 1953 (FEOLI

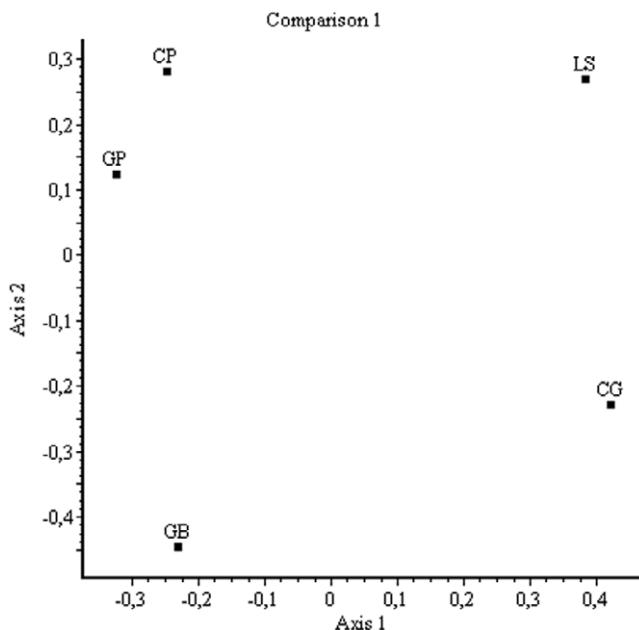

Fig. 11. Two-dimensional scatter-diagram of pioneer grassland and fringe vegetation (LS – *Leontodonti-Seslerietum calcariae*, CG – *Centaureo dichroanthae-Globularietum cordifoliae*, GB – *Gentianello pilosae-Brometum erecti*, CP – *Cirsio pannoniciae-Peucedanetum cervariae*, GP – *Geranio-Peucedanetum cervariae*) – PCoA, similarity ratio.

CHIAPELLA and POLDINI 1993), *Gentianello pilosae-Brometum erecti* Dakskobler et Završnik 2009 (DAKSKOBLER and ZAVRŠNIK 2009), and two thermophilic forest edge communities – *Cirsio pannoniciae-Peucedanetum cervariae* van Gils et al. 1975 (van GILS et al. 1975) and *Geranio-Peucedanetum cervariae* (KUHN 1937) T. Müller 1961 var. geogr. *Knautia drymeia* Čarni 1998 (ČARNI 1998) were ranged and compared using numerical methods. The results (Figs. 10, 11) clearly demonstrate that our stands are the most similar to the initial grassland on gravel sites of mountain rivers and streams in the foothills of the Southeastern Alps (association *Centaureo dichroanthae-Globularietum cordifoliae*) and are considerably different from thermophilic forest edge communities. Their floristic composition is also clearly different from riparian stands of the association *Gentianello pilosae-Brometum erecti*. This community is much more species-rich and grows on more developed soils, rendzinas. The stands of the association *Leontodonti brumatii-Seslerietum calcariae* are a successional stage in the afforestation of riparian rocks towards scrub and forest communities (*Seslerio albicanis-Ostryetum*, *Ostryo-Fagetum*). In addition to some meadow species they are mainly characterized by diagnostic species or rock crevices, screes and basophilic pine forests. Diagnostic species of the new association are *Leontodon hispidus* subsp. *brumatii*, *Sesleria caerulea* subsp. *calcaria*, *Calamagrostis varia*, *Hieracium porrifolium*, *Aster bellidiastrum* and *Athamanta turbith*. The holotypus of the new association is relevé No. 7 in table 2. The new association is classified as an explicitly fringe association (non-typical; with its species composition it is close also to the classes *Elyno-Sesleretea*, *Thlapietea rotundifolii* and *Asplenietea trichomanis*), into the Illyrian-pre-Alpine

suballiance *Centaurenion dichroanthae*, into the alliance *Saturejion subspicatae*, order *Scorzonero-Chrysopogoneta* and class *Festuco-Brometea*. It is subdivided into two subassociations. The differential species of the subassociation *Leontodonti-Seslerietum chamaecytisum purpureae* subass. nov. are *Chamaecytisus purpureus*, *Carex humilis*, *Allium ericetorum*, *Centaurea scabiosa* subsp. *fritschii* and *Inula ensifolia*. Its nomenclatural type is the *holotypus* of the association (relevé No. 7 in table 2); its sites are limestone riparian rocks. It is still flooded when the water level is high, but soil has already started accumulating in the runnels, which allows for a progressive development of the vegetation. The differential species of the subassociation *Leontodonti-Seslerietum saxifragetum crustatae* subass. nov. are *Saxifraga crustata*, *Erica carnea*, *Laserpitium prutenicum*, *Campanula cespitosa*, *Petasites paradoxus* and *Stachys recta*. The nomenclatural type, *holotypus*, is relevé No. 13 in table 2. The sites of this subassociation are steep, gravelly, erosion slopes on platy limestone with addition of chert on the northeastern slopes of Bučenica, some ten metres above the Soča between Tolmin and Most na Soči. The species composition indicates the development from a scree community through stony grassland into a thermophilic forest (*Ostryo-Fagetum*). The first three relevés in table 2 could not be classified into the new association. The floristic composition of relevé No. 1 in table 2 (rocky eyot in the Idrijca at Slap ob Idrijci) shows some similarities with the stands of the association *Triseto-Leontodontetum*, while relevés 2 and 3 in the same table represent a chasmophytic community, for the time being synsystematically still undefined, at the road cut between Podsela and Doblar, dominated by *Athamanta turbith*, *Campanula carnica* and *C. pyramidalis*.

Discussion

The new localities of the southeastern-Alpine endemic *Leontodon hispidus* subsp. *brumatii* in the Sava valley (central Slovenia, the Black Sea river basin), in the gorge of the Sava between the village of Sava and Zidani Most, are rather surprising, because so far this taxon was known in Slovenia only in the Soča basin (on riparian rocks along the Soča, Nadiža, Učja, Idrija and Idrijca), which belongs the Adriatic Sea river basin, but not along other Alpine rivers. Nevertheless, the new localities are situated in the region where quite a few species with predominantly Alpine distribution grow (e.g. *Rhododendron hirsutum*, *Paederota lutea*, *Pinguicula alpina*, *Rosa pendulina*, *Cerastium subtriflorum*, *Tephroseris pseudocrispia*, *Aster bellidiastrum*, *Campanula carnica*, *C. cespitosa*, *Trisetum argenteum*, *Arabis alpina* subsp. *alpina*, *Astrantia carniolica*, *Acinos alpinus*, *Aconitum degenii* subsp. *paniculatum*, *Tofieldia calyculata*, *Myrrhis odorata* – the latter is mentioned by PETKOVŠEK 1939). The flora of the Sava valley also comprises some species that most frequently occur in the Soča valley, but are usually much rarer in other landscape regions of Slovenia. Such species are for example *Saxifraga petraea*, *Veratrum nigrum*, *Hemerocallis lilioasphodelus*, *Spiraea chamaedryfolia*. There are also some similarities between the forest communities of valuable broad-leaved species (e.g. the probable occurrence of the stands of two associations described in the Soča valley, *Veratro nigri-Fraxinetum* and *Saxifrago petraeae-Tilietum*, also in the Sava valley). It is also likely that the taxon *L. brumatii* occurs on suitable sites elsewhere in the Sava basin (and other Slovenian Alpine rivers), but has been overlooked. Riparian sites are usually difficult to access and are therefore not the subject of a more detailed floristic inventory. The established differences in the communities

of *L. brumatii* between the Soča and the Sava valleys do not rule out the possibility that the stands of the association *Triseto-Leontodontetum* that was described in the Sava valley occur also in the Soča valley (which is very likely, because the sites in the Soča valley comprise a higher number of this endemic than those in the Sava valley). Similarly, the occurrence of the stands of the association *Leontodonti-Seslerietum* described in the Soča valley, is likely also in the Sava valley (already demonstrated in one of the relevés). Both newly described associations include phytocoenoses that are usually distributed in smaller areas and are more or less long-term successional stages. These are by nature subject to the river dynamics and can disappear from one spot only to reappear in another. They are extremely exposed to human interventions of any kind. The endemic *Leontodon brumatii* and its communities are a characteristic of riparian flora and vegetation of some of Slovenian mountain rivers. According to current knowledge, the localities in the Sava valley are explicitly disjunct and the southeasternmost in the entire known distribution area, so they deserve our attention and protection. The envisaged interventions along the central Sava, i.e. construction of new hydroelectric power plants, would most probably lead to destruction of suitable habitats for *Leontodon brumatii*. With a higher water level between Zagorje and Hrastnik, this endemic is likely to disappear from the river's riparian zone, as has probably already happened downstream, before Zidani Most or Radeče and further south.

Acknowledgements

The research in the Sava valley was conducted in the framework of the research programme Gradients and Biodiversity: Flora, Fauna and Vegetation (grant no. P1-0236), funded by Slovenian Research Agency, and of the assignment Inventory of plant species in the middle Sava area (commissioned by the HSE d.o.o.). Boško Čušin, MSc, helped us in the field. Associate professor Andraž Čarni, PhD and Urban Šilc, PhD, helped us with literature sources. Iztok Sajko prepared figures 1 and 2 for print. Sincere thanks to two anonymous reviewers for their helpful remarks, instructions, corrections and improvements. English translation by Andreja Šalamon Verbič.
